

**NAME**

vsearch — dereplicate, filter, sort, search, compare and clusterize amplicons from metagenomic projects

**SYNOPSIS**

Chimera detection:

```
vsearch [options] --uchime_denovo fastafile (--chimeras|--nonchimeras|--uchimealns|--uchimeout) outputfile
```

```
vsearch [options] --uchime_ref fastafile (--chimeras|--nonchimeras|--uchimealns|--uchimeout) outputfile --db fastafile
```

Clustering:

```
vsearch [options] (--cluster_fast|--cluster_smallmem) fastafile (--alnout|--blast6out|--centroids|--clusters|--msaout|--uc|--userout) outputfile --id real
```

Dereplication:

```
vsearch [options] --derep_fulllength fastafile (--output|--uc) outputfile
```

Masking:

```
vsearch [options] --maskfasta fastafile --output outputfile
```

Searching:

```
vsearch [options] --vsearch_global fastafile --db fastafile (--alnout|--blast6out|--uc|--userout) outputfile --id real
```

Shuffling:

```
vsearch [options] --shuffle fastafile --output outputfile
```

Sorting:

```
vsearch [options] (--sortbylength|--sortbysize) fastafile --output outputfile
```

**DESCRIPTION**

Environmental or clinical molecular studies generate large volumes of amplicons (e.g. SSU-rRNA sequences) that need to be dereplicated, filtered, sorted, searched, clusterized or compared to reference sequences. The aim of **vsearch** is to offer a all-in-one open source tool to perform these tasks, using optimized algorithm implementations and harvesting the full potential of modern computers, thus guaranteeing a fast and accurate data processing.

Nucleotidic sequence comparisons is at the core of **vsearch**. To speed up comparisons, **vsearch** implements an efficient *k*-mer filtering, and an extremely fast implementation of the Needleman-Wunsch algorithm, making use of the Streaming SIMD Extensions (SSE2) of modern x86-64 CPUs. If SSE2 instructions are not available, **vsearch** exits with an error message.

**Input**

**vsearch** input is a fasta file containing one or several nucleotidic sequences. For each sequence, the sequence identifier is defined as the string comprised between the ">" symbol and the first space, or the end of the line, whichever comes first. Additionally, if the line starts with (>[:]*size=integer*;label), contains (>label;*size=integer*;label) or ends with (>label;*size=integer*[:]), **vsearch** will remove the pattern [:]*size=integer*[:]; from the header and interpret *integer* as the number of occurrences (or abundance) of the sequence in the study. That abundance information is used or created during chimera detection, dereplication, sorting and searching.

The nucleotidic sequence is defined as a string of IUPAC symbols (ACGTURYSWKMDBHVN), starting after the end of the identifier line and ending before the next identifier line, or the file end. **vsearch** silently ignores ascii characters 9 to 13, and exits with an error message if ascii characters 0 to 8, 14 to 31, "." and "-" are present. All other ascii or non-ascii characters are stripped and complained about in a non-blocking warning message.

**vsearch** operations are case insensitive, except when soft masking is activated. For --vsearch\_global (searching), --cluster\_fast and --cluster\_smallmem (clustering), and --maskfasta (masking) commands, the case is important if soft masking is used. Soft masking is specified with the options "--dbmask soft" (for searching) or "--qmask soft" (for searching, clustering and masking). When using soft masking, lower case letters indicate masked symbols, while upper case letters indicate regular symbols. Masked symbols are never included in the unique *k*-mers used in searching. When soft masking is not activated, all letters are converted to upper case internally and used in result files.

When aligning sequences during searching and clustering, T and U are considered identical, regardless of their case. If two symbols are non-identical, their alignment will result in the negative mismatch score (default -4), except if one or both of the symbols are ambiguous (RYSWKMDBHVN) in which case the score is zero. Alignment of two identical ambiguous symbols (e.g. R vs R) also receives a score of zero.

Optionally, **vsearch** can be compiled to accepted compressed fasta files as input (gz and bzip2 formats).

## Options

**vsearch** recognizes a large number of command-line options. For an easier navigation, options are grouped by theme (chimera detection, clustering, dereplication, masking, shuffling, sorting, and searching). We start with general options that apply to all themes.

General options:

- help** display a short help and exit.
- version** output version information and exit.
- fasta\_width** *positive integer*  
fasta files produced by **vsearch** are wrapped (sequences are written on lines of *integer* nucleotides, 80 by default). Set that value to 0 to eliminate the wrapping.
- maxseqlength** *positive integer*  
all **vsearch** operations will discard sequences of length equal or greater than *integer* (50,000 nucleotides by default).
- minseqlength** *positive integer*  
all **vsearch** operations will discard sequences of length smaller than *integer* (1 nucleotide by default for sorting or shuffling, 32 nucleotides for clustering, dereplication or searching).
- notrunclabels**  
do not truncate sequence labels at first space, use the full header in output files.

Chimera detection options:

Chimera detection is based on a scoring function controlled by five options (**--dn**, **--mindiv**, **min-diffs**, **--minh**, **--xn**). Sequences are first sorted by decreasing abundance (if available), and compared on their *plus* strand only.

In *de novo* mode, input fasta file should present abundance annotations (pattern `[;]size=integer[;]` in the fasta header). The input order influences the chimera detection, we recommend to sort sequences by decreasing abundance (default of **--derep\_fulllength** command). If your sequence set needs to be sorted, please see the **--sortby** command in the sorting section.

- abskew** *real*  
when using **--uchime\_denovo**, the abundance skew is used to distinguish in a 3-way alignment which sequence is the chimera and which are the parents. The assumption is that chimeras appeared latter in the PCR amplification process and are therefore less abundant than their parents. The default value is 2.0, which means that the parents should be at least 2 times more abundant than their chimera. Any positive value greater than 1.0 can be used.
- chimeras** *filename*  
output chimeric sequences to *filename*, in fasta format. Output order may vary when using multiple threads.
- db** *filename*  
when using **--uchime\_ref**, detect chimeras using the fasta-formatted reference sequences contained in *filename*. Reference sequences are assumed to be chimera-free. Chimeras will not be detected if their parents (or sufficiently close relatives) are not present in the database.

- dn** *real* no vote pseudo-count (parameter *n* in the chimera scoring function) (1.4).
- mindiffs** *positive integer*  
minimum number of differences per segment (3).
- minh** *real*  
minimum score (h). Increasing this value tends to reduce the number of false positives and to decrease sensitivity. Default value is 0.28. (value ranging from 0.0 to 1.0 included).
- nonchimeras** *filename*  
output non-chimeric sequences to *filename*, in fasta format. Output order may vary when using multiple threads.
- rowlen** *positive integer*  
width of 3-way alignments in --uchimealns output. The default value is 80. Set to 0 to eliminate the wrapping.
- self** when using --uchime\_ref, ignore a reference sequence when its label matches the label of the query sequence (useful to estimate false-positive rate in reference sequences).
- selfid** when using --uchime\_ref, ignore a reference sequence when its nucleotidic sequence is strictly identical with the query sequence.
- uchime\_denovo** *filename*  
detect chimeras present in the fasta-formatted *filename*, without external references (i.e. *de novo*). Multithreading is not supported.
- uchime\_ref** *filename*  
detect chimeras present in the fasta-formatted *filename* by comparing them with reference sequences (option --db). Multithreading is supported.
- uchimealns** *filename*  
write 3-way global alignments (parentA, parentB, chimera) to *filename* using a human-readable format. Use --rowlen to modify alignment length. Output order may vary when using multiple threads.
- uchimeout** *filename*  
write chimera detection results to *filename* using the uchime tab-separated format of 18 fields (see the list below). Use --uchimeout5 to use a format compatible with usearch v5 and earlier versions. Rows output order may vary when using multiple threads.
1. score — higher score means a more likely chimeric alignment.
  2. Q — query sequence label.
  3. A — parent A sequence label.
  4. B — parent B sequence label.
  5. T — top parent sequence label (i.e. parent most similar to the query). That field is removed when using --uchimeout5.
  6. idQM — percentage of similarity of query (Q) and model (M) constructed as a segment of parent A and a segment of parent B.
  7. idQA — percentage of similarity of query (Q) and parent A.
  8. idQB — percentage of similarity of query (Q) and parent B.
  9. idAB — percentage of similarity of parent A and parent B.
  10. idQT — percentage of similarity of query (Q) and top parent (T).
  11. LY — yes votes in the left segment of the model.
  12. LN — no votes in the left segment of the model.

13. LA — abstain votes in the left segment of the model.
14. RY — yes votes in the right segment of the model.
15. RN — no votes in the right segment of the model.
16. RA — abstain votes in the right segment of the model.
17. div — divergence, defined as (idQM - idQT).
18. YN — query is chimeric (Y), or not (N), or is a borderline case (?).

**--uchimeout5**

when using **--uchimeout**, write chimera detection results using a tab-separated format of 17 fields (drop the 5th field of **--uchimeout**), compatible with usearch version 5 and earlier versions.

**--xn** *real* no vote weight (parameter  $\beta$ ) (8.0).

Clustering options:

**vsearch** implements a single-pass, greedy star-clustering algorithm, similar to the algorithms implemented in usearch, DNAClust and sumacust. Important parameters are the global clustering threshold (**--id**) and the pairwise identity definition (**--iddef**).

**--centroids** *filename*

output cluster centroid sequences to *filename* file, in fasta format. The centroid is the sequence that seeded the cluster (i.e. the first sequence of the cluster).

**--cluster\_fast** *filename*

clusterize the fasta sequences in *filename*, automatically perform a sorting by decreasing sequence length beforehand.

**--cluster\_smallmem** *filename*

clusterize the fasta sequences in *filename* without automatically modifying their order beforehand. Sequence are expected to be sorted by decreasing sequence length, unless **--usersort** is used.

**--clusters** *string*

output each cluster to a separate fasta file using the prefix *string* and a ticker (0, 1, 2, etc.) to construct the filenames.

**--consout** *filename*

output cluster consensus sequences to *filename*. For each cluster, a multiple alignment is computed, and a consensus sequence is constructed by taking the majority symbol (nucleotide or gap) from each column of the alignment. Columns containing a majority of gaps are skipped, except for terminal gaps. Use **--construncate** to take terminal gaps into account (not implemented yet).

**--id** *real* do not add the target to the cluster if the pairwise identity with the centroid is lower than *real* (value ranging from 0.0 to 1.0 included). The pairwise identity is defined as the number of (matching columns) / (alignment length - terminal gaps). That definition can be modified by **--iddef**.

**--iddef** 0/1/2/3/4

change the pairwise identity definition used in **--id**. Values accepted are:

0. CD-HIT definition using shortest sequence as numerator.
1. edit distance: (matching columns) / (alignment length).
2. edit distance excluding terminal gaps (default value).
3. Marine Biological Lab definition counting each extended gap as a single difference.

4. BLAST definition, equivalent to `--iddef 2` in a context of global pairwise alignment.

**--msaout** *filename*

output a multiple sequence alignment and a consensus sequence for each cluster to *filename*, in fasta format. The consensus sequence is constructed by taking the majority symbol (nucleotide or gap) from each column of the alignment. Columns containing a majority of gaps are skipped, except for terminal gaps. Use `--construncate` to take terminal gaps into account (not implemented yet).

**--qmask** *none/dust/soft*

mask simple repeats and low-complexity regions in sequences using the *dust* or the *soft* algorithms, or do not mask (*none*). Warning, when using *soft* masking, clustering becomes case sensitive. The default is to mask using *dust*.

**--threads** *positive integer*

number of computation threads to use (1 to 256). The number of threads should be lesser or equal to the number of available CPU cores. The default is to launch one thread per available logical core.

**--strand** *plus/both*

when comparing sequences with the cluster seed, check the *plus* strand only (default) or check *both* strands.

**--uc** *filename*

output clustering results in *filename* using a uclust-like format. See <http://www.drive5.com/usearch/manual/ucout.html> for a description of the format.

**--usersort**

when using `--cluster_smallmem`, allow to use any sequence input order, not only a decreasing length sorting.

Many searching options also apply to clustering:

`--alnout`, `--blast6out`, `--userout`, `--userfields`, `fastapairs`, `--matched`, `--notmatched`, `--max-accept`, `--maxreject`, score filtering, gap penalties, masking. (see the Searching section).

Dereplication options:

**--derep\_fulllength** *filename*

merge strictly identical sequences contained in *filename*. Identical sequences are defined as having the same length and the same string of nucleotides (case insensitive, T and U are considered as different). As **vsearch** needs to read *filename* twice, *filename* must be a real file, not a stream.

**--maxuniquesize** *positive integer*

discard sequences with an abundance value greater than *integer*.

**--minuniquesize** *positive integer*

discard sequences with an abundance value smaller than *integer*.

**--output** *filename*

write the dereplicated sequences to *filename*, in fasta format and sorted by decreasing abundance. Identical sequences receive the header of the first sequence of their group. If `--sizeout` is used, the number of occurrences (i.e. abundance) of each sequence is indicated at the end of their fasta header using the pattern `";size=integer"`.

**--sizein** take into account the abundance annotations present in the input fasta file (search for the pattern `"[>]size=integer[;]"` in sequence headers).

**--sizeout** add abundance annotations to the output fasta file (add the pattern `";size=integer"` to sequence headers).

**--strand** *plus/both*

when searching for strictly identical sequences, check the *plus* strand only (default) or check *both* strands.

**--topn** *positive integer*

output only the top *integer* sequences (i.e. the most abundant).

**--uc** *filename*

output dereplication results in *filename* using a uclust-like format. See <http://www.drive5.com/usearch/manual/ucout.html> for a description of the format. In the context of dereplication, the option `--uc_allhits` has no effect.

## Masking options:

An input sequence can be composed of lower- or uppercase nucleotides. Lowercase nucleotides are silently converted to uppercase before masking, unless the `--qmask soft` option is used. Here are the results of combined masking options `--qmask` (or `--dbmask` for database sequences) and `--hardmask`, assuming each input sequences contains both lower and uppercase nucleotides:

qmask	hardmask	action
none	off	no masking, lowercase converted to uppercase
none	on	idem
dust	off	masked symbols converted to lowercase, the rest converted to uppercase
dust	on	masked symbols replaced by Ns, the rest converted to upper case
soft	off	lowercase symbols considered masked, no case changes
soft	on	lowercase symbols considered masked and converted to Ns

**--hardmask**

mask low-complexity regions by replacing them with Ns instead of setting them to lower case.

**--maskfasta** *filename*

mask simple repeats and low-complexity regions in sequences contained in *filename*. The default is to mask using *dust* (use `--qmask` to modify that behavior).

**--qmask** *none/dust/soft*

mask simple repeats and low-complexity regions in sequences using the *dust* or the *soft* algorithms, or do not mask (*none*). The default is to mask using *dust*.

**--output** *filename*

write the masked sequences to *filename*, in fasta format.

**--threads** *positive integer*

number of computation threads to use (1 to 256). The number of threads should be lesser or equal to the number of available CPU cores. The default is to launch one thread per available logical core.

## Searching options:

**--alnout** *filename*

write pairwise global alignments to *filename* using a human-readable format. Use `--rowlen` to modify alignment length. Output order may vary when using multiple threads.

**--blast6out** *filename*

write search results to *filename* using a blast-like tab-separated format of twelve fields (listed below), with one line per query-target matching (or lack of matching if `--output_no_hits` is used). Output order may vary when using multiple threads. A similar output can be obtain with `--userout filename` and `--userfields query+target+id+alrlen+mism+opens+qlo+qhi+tlo+thi+evalue+bits`. A complete list and description is available in the section "Fields" of this manual.

1. *query*: query label.
2. *target*: target (database sequence) label. The field is set to "\*" if there is no alignment.
3. *id*: percentage of identity (real value ranging from 0.0 to 100.0). The percentage identity is defined as  $100 * (\text{matching columns}) / (\text{alignment length} - \text{terminal gaps})$ . See fields *id0* to *id4* for other definitions.
4. *alnlen*: length of the query-target alignment (number of columns). The field is set to 0 if there is no alignment.
5. *mism*: number of mismatches in the alignment (zero or positive integer value).
6. *opens*: number of columns containing a gap opening (zero or positive integer value).
7. *qlo*: first nucleotide of the query aligned with the target. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.
8. *qhi*: last nucleotide of the query aligned with the target. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.
9. *tlo*: first nucleotide of the target aligned with the query. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.
10. *thi*: last nucleotide of the target aligned with the query. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.
11. *eval*: expectancy-value (not computed for nucleotidic alignments). Always set to -1.
12. *bits*: bit score (not computed for nucleotidic alignments). Always set to 0.

**--db** *filename*

compare query sequences (--vsearch\_global) to the fasta-formatted target sequences contained in *filename*, using global pairwise alignment.

**--dbmask** *none|dust|soft*

mask simple repeats and low-complexity regions in target database sequences using the *dust* or the *soft* algorithms, or do not mask (*none*). Warning, when using *soft* masking search commands become case sensitive. The default is to mask using *dust*.

**--dbmatched** *filename*

write database target sequences matching at least one query sequence to *filename*, in fasta format. If the option --sizeout is used, the number of queries that matched each target sequence is indicated using the pattern ";size=*integer*".

**--dbnotmatched** *filename*

write database target sequences not matching query sequences to *filename*, in fasta format.

**--fastapairs** *filename*

write pairwise alignments of query and target sequences to *filename*, in fasta format.

**--fulldp**

dummy option. To maximize search sensitivity, **vsearch** uses a 8-way 16-bit SIMD vectorized full dynamic programming algorithm (Needleman-Wunsch), whether or not --fulldp is specified.

**--gapext** *string*

set penalties for a gap extension. See --gapopen for a complete description of the penalty declaration system. The default is to initialize the six gap extending penalties using a penalty of 2 for extending internal gaps and a penalty of 1 for extending terminal gaps, in both query and target sequences (i.e. 2I/1E).

**--gapopen** *string*

set penalties for a gap opening. A gap opening can occur in six different contexts: in the query (Q) or in the target (T) sequence, at the left (L) or right (R) extremity of the sequence, or inside the sequence (I). Sequence symbols (Q and T) can be combined with location symbols (L, I, and R), and numerical values to declare penalties for all possible contexts: aQL/bQI/cQR/dTL/eTI/fTR, where abcdef are null or positive integers, and "/" is use as separator.

To simplify declarations, the location symbols (L, I, and R) can be combined, the symbol (E) can be used to treat both extremities (L and R) equally, and the symbols Q and T can be omitted to treat both sequences equally. For instance, the default is to declare a penalty of 20 for opening internal gaps and a penalty of 2 for opening terminal gaps (left or right), in both query and target sequences (i.e. 20I/2E). If only a numerical value is given, without any sequence or location symbol, then the penalty applies to all gap openings. To declare an infinite penalty value, the symbol "\*" can be used to indicate that gap openings are forbidden in that context.

**vsearch** always initializes the six gap opening penalties using the default parameters (20I/2E). The user is then free to declare only the values he wants to modify. The *string* is scanned from left to right, accepted symbols are (0123456789/LIREQT\*), and later values override previous values.

**--hardmask**

mask low-complexity regions by replacing them with Ns instead of setting them to lower case. For more information, please see the Masking section.

**--id** *real* reject the sequence match if the pairwise identity is lower than *real* (value ranging from 0.0 to 1.0 included). The search process sorts target sequences by decreasing number of *k*-mers they have in common with the query sequence, using that information as a proxy for sequence similarity. That efficient pre-filtering will also prevent pairwise alignments with weakly matching targets, as there needs to be at least 6 shared *k*-mers to start the pairwise alignment, and at least one out of every 16 *k*-mers from the query needs to match the target. Consequently, using values lower than --id 0.5 is not likely to capture more weakly matching targets. The pairwise identity is defined as the number of (matching columns) / (alignment length - terminal gaps). That definition can be modified by --iddef.

**--iddef** 0/1/2/3/4

change the pairwise identity definition used in --id. Values accepted are:

0. CD-HIT definition using shortest sequence as numerator.
1. edit distance.
2. edit distance excluding terminal gaps (default value of --id).
3. Marine Biological Lab definition counting each extended gap as a single difference.
4. BLAST definition, equivalent to --iddef 2 in a context of global pairwise alignment.

The option --userfields accepts the fields id0 to id4, in addition to the field id, to report the pairwise identity values corresponding to the different definitions.

**--idprefix** *positive integer*

reject the target sequence if the first *integer* nucleotides do not match the query sequence.

**--idsuffix** *positive integer*

reject the target sequence if the last *integer* nucleotides do not match the query sequence.

- leftjust** reject the target sequence if the alignment begins with gaps.
- match** *integer*  
score assigned to a match (i.e. identical nucleotides) in the pairwise alignment. The default value is 2.
- matched** *filename*  
write query sequences matching database target sequences to *filename*, in fasta format.
- maxaccepts** *positive integer*  
maximum number of hits to accept before stopping the search. The default value is 1. That option works in pair with maxrejects. The search process sorts target sequences by decreasing number of *k*-mers they have in common with the query sequence, using that information as a proxy for sequence similarity. If the first target sequence passes the acceptance criteria, it is accepted as best hit and the search process stops for that query. If maxaccepts is set to a higher value, more hits are accepted. If maxaccepts and maxrejects are both set to 0, the complete database is searched.
- maxdiffs** *positive integer*  
reject the target sequence if the alignment contains at least *integer* substitutions, insertions or deletions.
- maxgaps** *positive integer*  
reject the target sequence if the alignment contains at least *integer* insertions or deletions.
- maxhits** *positive integer*  
maximum number of hits to show once the search is terminated (hits are sorted by decreasing identity). Unlimited by default value. **It applies to alnout, blast6out, uc, userout, fastapairs.**
- maxid** *real*  
reject the target sequence if its percentage of identity with the query is equal to or greater than *real*.
- maxqsize** *positive integer*  
reject query sequences with an abundance equal to or greater than *integer*.
- maxqt** *real*  
reject if the query/target sequence length ratio is equal to or greater than *real*.
- maxrejects** *positive integer*  
maximum number of non-matching target sequences to consider before stopping the search. The default value is 32. That option works in pair with maxaccepts. The search process sorts target sequences by decreasing number of *k*-mers they have in common with the query sequence, using that information as a proxy for sequence similarity. If none of the first 32 target sequences pass the acceptance criteria, the search process stops for that query (no hit). If maxrejects is set to a higher value, more target sequences are considered. If maxaccepts and maxrejects are both set to 0, the complete database is searched.
- maxsizeratio** *real*  
reject if the query/target abundance ratio is equal to or greater than *real*.
- maxsl** *real*  
reject if the shorter/longer sequence length ratio is equal to or greater than *real*.
- maxsubs** *positive integer*  
reject the target sequence if the alignment contains at least *integer* substitutions.
- mid** *real*  
reject the alignment if the percentage of identity is lower than *real* (ignoring all gaps, internal and terminal).

- mincols** *positive integer*  
reject the target sequence if the alignment length is shorter than *integer*.
- minqt** *real*  
reject if the query/target sequence length ratio is lower than *real*.
- minsizeratio** *real*  
reject if the query/target abundance ratio is lower than *real*.
- minsl** *real*  
reject if the shorter/longer sequence length ratio is lower than *real*.
- mintsize** *positive integer*  
reject target sequences with an abundance lower than *integer*.
- mismatch** *integer*  
score assigned to a mismatch (i.e. different nucleotides) in the pairwise alignment. The default value is -4.
- notmatched** *filename*  
write query sequences not matching database target sequences to *filename*, in fasta format.
- output\_no\_hits**  
write both matching and non-matching queries to --alnout, --blast6out, and --userout output files (--uc and --uc\_allhits output files always feature non-matching queries). Non-matching queries are labelled "No hits" in --alnout files.
- qmask** *none/dust/soft*  
mask simple repeats and low-complexity regions in query sequences using the *dust* or the *soft* algorithms, or do not mask (*none*). Warning, when using *soft* masking search commands become case sensitive. The default is to mask using *dust*.
- query\_cov** *real*  
reject if the fraction of the query aligned to the target sequence is lower than *real*. The query coverage is computed as such:  $100.0 * (\text{matches} + \text{mismatches}) / \text{query sequence length}$ . Internal or terminal gaps are not taken into account.
- rightjust**  
reject the target sequence if the alignment ends with gaps.
- rowlen** *positive integer*  
width of alignment lines in --alnout output. The default value is 64. Set to 0 to eliminate the wrapping.
- self**  
reject the alignment if the query and target labels are identical.
- selfid**  
reject the alignment if the query and target sequences are strictly identical.
- sizeout**  
add abundance annotations to the output of the option --dbmatched (using the pattern ";size=*integer*").
- strand** *plus/both*  
when searching for similar sequences, check the *plus* strand only (default) or check *both* strands.
- target\_cov** *real*  
reject if the fraction of the target sequence aligned to the query sequence is lower than *real*. The target coverage is computed as such:  $100.0 * (\text{matches} + \text{mismatches}) / \text{target sequence length}$ . Internal or terminal gaps are not taken into account.
- threads** *positive integer*  
number of computation threads to use (1 to 256). The number of threads should be lesser or equal to the number of available CPU cores. The default is to launch one thread per available logical core.

**--top\_hits\_only**

output only the hits with the highest percentage of identity with the query.

**--uc** *filename*

output searching results in *filename* using a uclust-like format. See <http://www.drive5.com/usearch/manual/ucout.html> for a description of the format. Output order may vary when using multiple threads.

**--uc\_allhits**

when using the --uc option, show all hits, not just the top hit for each query. **TO BE TESTED.**

**--userfields** *string*

when using --userout, select and order the fields written to the output file. Fields are separated by "+" (e.g. query+target+id). See the "Userfields" section for a complete list of fields.

**--userout** *filename*

write user-defined tab-separated output to *filename*. Select the fields with the option --userfields. Output order may vary when using multiple threads. If --userfields is empty or not present, *filename* is empty.

**--vsearch\_global** *filename*

compare target sequences (--db) to the fasta-formatted query sequences contained in *filename*, using global pairwise alignment.

**--weak\_id** *real*

show hits with percentage of identity of at least *real*, without terminating the search. A normal search stops as soon as enough hits are found (as defined by --maxaccepts, --maxrejects, and --id). As --weak\_id reports weak hits that are not deduced from --maxaccepts, high --id values can be used, hence preserving both speed and sensitivity. Logically, *real* must be smaller than the value indicated by --id.

**--wordlength** *positive integer*

length of words (i.e. *k*-mers) for database indexing. The range of possible values goes from 3 to 15, but values near 8 are generally recommended. Longer words may reduce the sensitivity for weak similarities, but can increase accuracy. On the other hand, shorter words may increase sensitivity, but can reduce accuracy. Computation time will generally increase with shorter words and decrease with longer words. Memory requirements for a part of the index increase with a factor of 4 each time word length increases by one nucleotide, and this generally becomes significant for long words (12 or more). The default value is 8.

Shuffling options:

**--output** *filename*

write the shuffled sequences to *filename*, in fasta format.

**--seed** *positive integer*

when shuffling sequence order, use *integer* as seed. A given seed will always produce the same output order (useful for replicability). Set to 0 to use a pseudo-random seed (default behavior).

**--shuffle** *filename*

pseudo-randomly shuffle the order of sequences contained in *filename*.

**--topn** *positive integer*

output only the top *integer* sequences.

Sorting options:

- maxsize** *positive integer*  
when using --sortbysize, discard sequences with an abundance value greater than *integer*.
- minsize** *positive integer*  
when using --sortbysize, discard sequences with an abundance value smaller than *integer*.
- output** *filename*  
write the sorted sequences to *filename*, in fasta format.
- relabel** *string*  
relabel sequence using the prefix *string* and a ticker (1, 2, 3, etc.) to construct the new headers. Use --sizeout to conserve the abundance annotations.
- sizeout** when using --relabel, report abundance annotations to the output fasta file (using the pattern ";size=*integer*").
- sortbylength** *filename*  
sort by decreasing length the sequences contained in *filename*. See the general options --minseqlength and --maxseqlength to eliminate short and long sequences.
- sortbysize** *filename*  
sort by decreasing abundance the sequences contained in *filename* (the pattern "[>]size=*integer*[:]" has to be present). See the options --minsize and --maxsize to eliminate rare and dominant sequences.
- topn** *positive integer*  
output only the top *integer* sequences (i.e. the longest or the most abundant).

Userfields (fields accepted by the --userfields option):

- aln** Print a string of M (match), D (delete, i.e. a gap in the query) and I (insert, i.e. a gap in the target) representing the pairwise alignment. Empty field if there is no alignment.
- alnlen** Print the length of the query-target alignment (number of columns). The field is set to 0 if there is no alignment.
- bits** Bit score (not computed for nucleotidic alignments). Always set to 0.
- caln** Compact representation of the pairwise alignment using the CIGAR format (Compact Idiosyncratic Gapped Alignment Report): M (match), D (deletion) and I (insertion). Empty field if there is no alignment.
- evaluate** E-value (not computed for nucleotidic alignments). Always set to -1.
- exts** Number of columns containing a gap extension (zero or positive integer value).
- gaps** Number of columns containing a gap (zero or positive integer value).
- id** Percentage of identity (real value ranging from 0.0 to 100.0). The percentage identity is defined as  $100 * (\text{matching columns}) / (\text{alignment length} - \text{terminal gaps})$ .
- id0** CD-HIT definition of the percentage of identity, using the shortest sequence in the pairwise alignment as numerator (real value ranging from 0.0 to 100.0).
- id1** The percentage of identity (real value ranging from 0.0 to 100.0) is defined as the edit distance:  $100 * (\text{matching columns}) / (\text{alignment length})$ .
- id2** The percentage of identity (real value ranging from 0.0 to 100.0) is defined as the edit distance, excluding terminal gaps. The field id2 is an alias for the field id.
- id3** Marine Biological Lab definition of the percentage of identity (real value ranging from 0.0 to 100.0), counting each extended gap as a single difference.
- id4** BLAST definition of the percentage of identity (real value ranging from 0.0 to 100.0), equivalent to --iddef 2 in a context of global pairwise alignment.

<b>ids</b>	Number of matches in the alignment (zero or positive integer value).
<b>mism</b>	Number of mismatches in the alignment (zero or positive integer value).
<b>opens</b>	Number of columns containing a gap opening (zero or positive integer value).
<b>pairs</b>	Number of columns containing only nucleotides. That value corresponds to the length of the alignment minus the gap-containing columns (zero or positive integer value).
<b>pctgaps</b>	Number of columns containing gaps expressed as a percentage of the alignment length (real value ranging from 0.0 to 100.0).
<b>pctpv</b>	Percentage of positive columns. When working with nucleotidic sequences, this is equivalent to the percentage of matches (real value ranging from 0.0 to 100.0).
<b>pv</b>	Number of positive columns. When working with nucleotidic sequences, this is equivalent to the number of matches (zero or positive integer value).
<b>qcov</b>	Fraction of the query sequence that is aligned with the target sequence (real value ranging from 0.0 to 100.0). The query coverage is computed as such: $100.0 * (\text{matches} + \text{mismatches}) / \text{query sequence length}$ . Internal or terminal gaps are not taken into account. The field is set to 0.0 if there is no alignment.
<b>qframe</b>	Query frame (-3 to +3). That field only concerns coding sequences and is not computed by <b>vsearch</b> . Always set to +0.
<b>qhi</b>	Last nucleotide of the query aligned with the target. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.
<b>ql</b>	Query sequence length (positive integer value). The field is set to 0 if there is no alignment.
<b>qlo</b>	First nucleotide of the query aligned with the target. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.
<b>qrow</b>	Print the sequence of the query segment as seen in the pairwise alignment (i.e. with gap insertions if need be). Empty field if there is no alignment.
<b>qs</b>	Query segment length. Always equal to query sequence length.
<b>qstrand</b>	Query strand orientation (+ or - for nucleotidic sequences). Empty field if there is no alignment.
<b>query</b>	Query label.
<b>raw</b>	Raw alignment score (negative, null or positive integer value). The score is the sum of match rewards minus mismatch penalties, gap openings and gap extensions. The field is set to 0 if there is no alignment.
<b>target</b>	Target label. The field is set to "*" if there is no alignment.
<b>tcov</b>	Fraction of the target sequence that is aligned with the query sequence (real value ranging from 0.0 to 100.0). The target coverage is computed as such: $100.0 * (\text{matches} + \text{mismatches}) / \text{target sequence length}$ . Internal or terminal gaps are not taken into account. The field is set to 0.0 if there is no alignment.
<b>tframe</b>	Target frame (-3 to +3). That field only concerns coding sequences and is not computed by <b>vsearch</b> . Always set to +0.
<b>thi</b>	Last nucleotide of the target aligned with the query. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.
<b>tl</b>	Target sequence length (positive integer value). The field is set to 0 if there is no alignment.
<b>tlo</b>	First nucleotide of the target aligned with the query. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.

<b>trow</b>	Print the sequence of the target segment as seen in the pairwise alignment (i.e. with gap insertions if need be). Empty field if there is no alignment.
<b>ts</b>	Target segment length. Always equal to target sequence length. The field is set to 0 if there is no alignment.
<b>tstrand</b>	Target strand orientation (+ or - for nucleotidic sequences). Always set to "+", so reverse strand matches have tstrand "+" and qstrand "-". Empty field if there is no alignment.

## DELIBERATE CHANGES

If you are a usearch user, our objective is to make you feel at home. That's why **vsearch** was designed to behave like usearch, to some extent. Like any complex software, usearch is not free from quirks and inconsistencies. We decided not to reproduce some of them, and for complete transparency, to document here the deliberate changes we made.

During a search with usearch, when using the options `--blast6out` and `--output_no_hits`, for queries with no match the number of fields reported is 13, where it should be 12. This is corrected in **vsearch**.

The fields `qlo`, `qhi`, `tlo`, `thi` and `raw` of the `--userfields` option are not informative in usearch. This is corrected in **vsearch**.

In usearch, when using the option `--output_no_hits`, queries that receive no match are reported in `blast6out` file, but not in the alignment output file. This is corrected in **vsearch**.

**vsearch** reintroduces with `--iddef` alternative pairwise identity definitions that were removed from usearch.

**vsearch** extends the `--topn` option to sorting commands.

**vsearch** extends the `--rowlen` option to the chimera command (`--uchimealns` option).

## NOVELTIES

**vsearch** introduces new options not present in usearch. They are described in the "Options" section of this manual. Here is a short list:

- `shuffle`
- `fasta_width`
- `iddef`
- `maxuniquesize`

## EXAMPLES

Clusterize with a 97% similarity threshold, collect cluster centroids, and write cluster descriptions using a `uclust`-like format:

```
vsearch --cluster_fast queries.fas --id 0.97 --centroids centroids.fas --uc clusters.uc
```

Dereplicate the sequences contained in `queries.fas`, take into account the abundance information already present, write unwrapped sequences to output with the new abundance information, discard all sequences with an abundance of 1:

```
vsearch --derep_fulllength queries.fas --output queries_masked.fas --sizein --sizeout --fasta_width 0 --minuniquesize 2
```

Mask simple repeats and low complexity regions in the input fasta file (masked regions are lowercased), and write the results to the output file:

```
vsearch --maskfasta queries.fas --output queries_masked.fas --qmask soft
```

Sort by decreasing abundance the sequences contained in `queries.fas` (using the `"size=integer"` information), relabel the sequences while preserving the abundance information (with `--sizeout`), keep only sequences with an abundance equal to or greater than 2:

```
vsearch --sortbysize queries.fas --output queries_sorted.fas --relabel sampleA_ --sizeout --min-size 2
```

Search queries in a reference database, with a 80%-similarity threshold, take terminal gaps into account

when calculating pairwise similarities:

```
vsearch --vsearch_global queries.fas --db references.fas --alnout results.aln --id 0.8 --iddef 1
```

Search a sequence dataset against itself (ignore self hits), get all matches with at least 60% identity, and collect results in a blast-like tab-separated format:

```
vsearch --vsearch_global queries.fas --db queries.fas --id 0.6 --self --blast6out results.blast6  
--maxaccepts 0 --maxrejects 0
```

Shuffle the input fasta file (change the order of sequences) in a repeatable fashion (fixed seed), and write unwrapped fasta sequences to the output file:

```
vsearch --shuffle queries.fas --output queries_shuffled.fas --seed 13 --fasta_width 0
```

## LIMITATIONS

**vsearch** does not yet perform chimera detection.

## AUTHORS

Implementation by Torbjørn Rognes and Tomas Flouri, documentation by Frédéric Mahé.

## REPORTING BUGS

Submit suggestions and bug-reports at <<https://github.com/torognes/vsearch/issues>>, send a pull request on <<https://github.com/torognes/vsearch>>, or compose a friendly or curmudgeont e-mail to Torbjørn Rognes <[torognes@ifi.uio.no](mailto:torognes@ifi.uio.no)>.
