NAME

vsearch — dereplicate, filter, sort, search, compare and clusterize amplicons from metagenomic projects

SYNOPSIS

Chimera detection:

vsearch [options] --uchime_denovo fastafile (--chimeras|--nonchimeras|--uchimealns|--uchimeout) outputfile

vsearch [options] --uchime_ref fastafile (--chimeras|--nonchimeras|--uchimealns|--uchimeout) outputfile --db fastafile

Clustering:

vsearch [options] (--cluster_fast|--cluster_smallmem) fastafile (--alnout|--blast6out|--centroids|--clusters|--msaout|--uc|--userout) outputfile --id real

Dereplication:

vsearch [options] --derep_fulllength fastafile (--output|--uc) outputfile

Masking:

vsearch [options] --maskfasta fastafile --output outputfile

Searching:

vsearch [options] --vsearch_global fastafile --db fastafile (--alnout|--blast6out|--uc|--userout) outputfile --id real

Shuffling:

vsearch [options] --shuffle fastafile --output outputfile

Sorting:

vsearch [options] (--sortbylength|--sortbysize) fastafile --output outputfile

DESCRIPTION

Environmental or clinical molecular studies generate large volumes of amplicons (e.g. SSU-rRNA sequences) that need to be dereplicated, filtered, sorted, searched, clusterized or compared to reference sequences. The aim of **vsearch** is to offer a all-in-one open source tool to perform these tasks, using optimized algorithm implementations and harvesting the full potential of modern computers, thus guaranteeing a fast and accurate data processing.

Nucleotidic sequence comparisons is at the core of **vsearch**. To speed up comparisons, **vsearch** implements an efficient *k*-mer filtering, and an extremely fast implementation of the Needleman-Wunsch algorithm, making use of the Streaming SIMD Extensions (SSE2) of modern x86-64 CPUs. If SSE2 instructions are not available, **vsearch** exits with an error message.

Input

vsearch input is a fasta file containing one or several nucleotidic sequences. For each sequence, the sequence identifier is defined as the string comprised between the ">" symbol and the first space, or the end of the line, whichever comes first. Additionally, if the line starts with (>[;]size=integer;label), contains (>label;size=integer;label) or ends with (>label;size=integer[;]), **vsearch** will remove the pattern [;]size=integer[;] from the header and interpret integer as the number of occurrences (or abundance) of the sequence in the study. That abundance information is used or created during chimera detection, dereplication, sorting and searching.

The nucleotidic sequence is defined as a string of IUPAC symbols (ACGTURYSWKMDBHVN), starting after the end of the identifier line and ending before the next identifier line, or the file end. **vsearch** silently ignores ascii characters 9 to 13, and exits with an error message if ascii characters 0 to 8, 14 to 31, "." and "-" are present. All other ascii or non-ascii characters are stripped and complained about in a non-blocking warning message.

vsearch operations are case insensitive, except when soft masking is activated. For --vsearch_global (searching), --cluster_fast and --cluster_smallmem (clustering), and --maskfasta (masking) commands, the case is important if soft masking is used. Soft masking is specified with the options "--dbmask soft" (for searching) or "--qmask soft" (for searching, clustering and masking). When using soft masking, lower case letters indicate masked symbols, while upper case letters indicate regular symbols. Masked symbols are never included in the unique *k*-mers used in searching. When soft masking is not activated, all letters are converted to upper case internally and used in result files.

When aligning sequences during searching and clustering, T and U are considered identical, regardless of their case. If two symbols are non-identical, their alignment will result in the negative mismatch score (default -4), except if one or both of the symbols are ambiguous (RYSWKMDBHVN) in which case the score is zero. Alignment of two identical ambiguous symbols (e.g. R vs R) also receives a score of zero.

Optionally, vsearch can be compiled to accepted compressed fasta files as input (gz and bzip2 formats).

Options

vsearch recognizes a large number of command-line options. For an easier navigation, options are grouped by theme (chimera detection, clustering, dereplication, masking, shuffling, sorting, and searching). We start with general options that apply to all themes.

General options:

- **--help** display a short help and exit.
- --version output version information and exit.
- --fasta_width positive integer

fasta files produced by **vsearch** are wrapped (sequences are written on lines of *integer* nucleotides, 80 by default). Set that value to 0 to eliminate the wrapping.

--maxseqlength positive integer

all **vsearch** operations will discard sequences of length equal or greater than *integer* (50,000 nucleotides by default).

--minseqlength positive integer

all **vsearch** operations will discard sequences of length smaller than *integer* (1 nucleotide by default for sorting or shuffling, 32 nucleotides for clustering, dereplication or searching).

--notrunclabels

do not truncate sequence labels at first space, use the full header in output files.

Chimera detection options:

Chimera detection is based on a scoring function controlled by five options (--dn, --mindiv, mindiffs, --minh, --xn). Sequences are first sorted by decreasing abundance (if available), and compared on their *plus* strand only.

In *de novo* mode, input fasta file should present abundance annotations (pattern [;]size=*integer*[;] in the fasta header). The input order influences the chimera detection, we recommend to sort sequences by decreasing abundance (default of --derep_fulllength command). If your sequence set needs to be sorted, please see the --sortbysize command in the sorting section.

--abskew real

when using --uchime_denovo, the abundance skew is used to distinguish in a 3-way alignment which sequence is the chimera and which are the parents. The assumption is that chimeras appeared latter in the PCR amplification process and are therefore less abundant than their parents. The default value is 2.0, which means that the parents should be at least 2 times more abundant than their chimera. Any positive value greater than 1.0 can be used.

--chimeras filename

output chimeric sequences to *filename*, in fasta format. Output order may vary when using multiple threads.

--db filename

when using --uchime_ref, detect chimeras using the fasta-formatted reference sequences contained in *filename*. Reference sequences are assumed to be chimera-free. Chimeras will not be detected if their parents (or sufficiently close relatives) are not present in the database.

--dn real no vote pseudo-count (parameter n in the chimera scoring function) (1.4).

--mindiffs positive integer

minimum number of differences per segment (3).

--minh real

minimum score (h). Increasing this value tends to reduce the number of false positives and to decrease sensitivity. Default value is 0.28. (value ranging from 0.0 to 1.0 included).

--nonchimeras filename

output non-chimeric sequences to *filename*, in fasta format. Output order may vary when using multiple threads.

--rowlen positive integer

width of 3-way alignments in --uchimealns output. The default value is 80. Set to 0 to eliminate the wrapping.

--self when using --uchime_ref, ignore a reference sequence when its label matches the label of the query sequence (useful to estimate false-positive rate in reference sequences).

--selfid when using --uchime_ref, ignore a reference sequence when its nucleotidic sequence is strictly identical with the query sequence.

--uchime_denovo filename

detect chimeras present in the fasta-formatted *filename*, without external references (i.e. *de novo*). Multithreading is not supported.

--uchime_ref filename

detect chimeras present in the fasta-formatted *filename* by comparing them with reference sequences (option --db). Multithreading is supported.

--uchimealns filename

write 3-way global alignments (parentA, parentB, chimera) to *filename* using a human-readable format. Use --rowlen to modify alignment length. Output order may vary when using multiple threads.

--uchimeout filename

write chimera detection results to *filename* using the uchime tab-separated format of 18 fields (see the list below). Use --uchimeout5 to use a format compatible with usearch v5 and earlier versions. Rows output order may vary when using multiple threads.

- 1. score higher score means a more likely chimeric alignment.
- 2. Q query sequence label.
- 3. A parent A sequence label.
- 4. B parent B sequence label.
- 5. T top parent sequence label (i.e. parent most similar to the query). That field is removed when using --uchimeout5.
- 6. idQM percentage of similarity of query (Q) and model (M) constructed as a segment of parent A and a segment of parent B.
- 7. idQA percentage of similarity of query (Q) and parent A.
- 8. idQB percentage of similarity of query (Q) and parent B.
- 9. idAB percentage of similarity of parent A and parent B.
- 10. idQT percentage of similarity of query (Q) and top parent (T).
- 11. LY yes votes in the left segment of the model.
- 12. LN no votes in the left segment of the model.

- 13. LA abstain votes in the left segment of the model.
- 14. RY yes votes in the right segment of the model.
- 15. RN no votes in the right segment of the model.
- 16. RA abstain votes in the right segment of the model.
- 17. div divergence, defined as (idQM idQT).
- 18. YN query is chimeric (Y), or not (N), or is a borderline case (?).

--uchimeout5

when using --uchimeout, write chimera detection results using a tab-separated format of 17 fields (drop the 5th field of --uchimeout), compatible with usearch version 5 and earlier versions.

--xn real no vote weight (parameter β) (8.0).

Clustering options:

vsearch implements a single-pass, greedy star-clustering algorithm, similar to the algorithms implemented in usearch, DNAclust and sumaclust. Important parameters are the global clustering threshold (--id) and the pairwise identity definition (--iddef).

--centroids filename

output cluster centroid sequences to *filename* file, in fasta format. The centroid is the sequence that seeded the cluster (i.e. the first sequence of the cluster).

--cluster fast filename

clusterize the fasta sequences in *filename*, automatically perform a sorting by decreasing sequence length beforehand.

--cluster smallmem filename

clusterize the fasta sequences in *filename* without automatically modifying their order beforehand. Sequence are expected to be sorted by decreasing sequence length, unless --usersort is used.

-- clusters string

output each cluster to a separate fasta file using the prefix *string* and a ticker (0, 1, 2, etc.) to construct the filenames.

--consout filename

output cluster consensus sequences to *filename*. For each cluster, a multiple alignment is computed, and a consensus sequence is constructed by taking the majority symbol (nucleotide or gap) from each column of the alignment. Columns containing a majority of gaps are skipped, except for terminal gaps. Use --construncate to take terminal gaps into account (not implemented yet).

--id *real* do not add the target to the cluster if the pairwise identity with the centroid is lower than *real* (value ranging from 0.0 to 1.0 included). The pairwise identity is defined as the number of (matching columns) / (alignment length - terminal gaps). That definition can be modified by --iddef.

--iddef 0/1/2/3/4

change the pairwise identity definition used in --id. Values accepted are:

- 0. CD-HIT definition using shortest sequence as numerator.
- 1. edit distance: (matching columns) / (alignment length).
- 2. edit distance excluding terminal gaps (default value).
- 3. Marine Biological Lab definition counting each extended gap as a single difference.

4. BLAST definition, equivalent to --iddef 2 in a context of global pairwise alignment.

--msaout filename

output a multiple sequence alignment and a consensus sequence for each cluster to *file-name*, in fasta format. The consensus sequence is constructed by taking the majority symbol (nucleotide or gap) from each column of the alignment. Columns containing a majority of gaps are skipped, except for terminal gaps. Use --construncate to take terminal gaps into account (not implemented yet).

--qmask none/dust/soft

mask simple repeats and low-complexity regions in sequences using the *dust* or the *soft* algorithms, or do not mask (*none*). Warning, when using *soft* masking, clustering becomes case sensitive. The default is to mask using *dust*.

--threads positive integer

number of computation threads to use (1 to 256). The number of threads should be lesser or equal to the number of available CPU cores. The default is to launch one thread per available logical core.

--strand plus/both

when comparing sequences with the cluster seed, check the *plus* strand only (default) or check *both* strands.

--uc filename

output clustering results in *filename* using a uclust-like format. See http://www.drive5.com/usearch/manual/ucout.html for a description of the format.

--usersort

when using --cluster_smallmem, allow to use any sequence input order, not only a decreasing length sorting.

Many searching options also apply to clustering:

--alnout, --blast6out, --userout, --userfields, fastapairs, --matched, --notmatched, --max-accept, --maxreject, score filtering, gap penalties, masking. (see the Searching section).

Dereplication options:

--derep_fulllength filename

merge strictly identical sequences contained in *filename*. Identical sequences are defined as having the same length and the same string of nucleotides (case insensitive, T and U are considered as different). As **vsearch** needs to read *filename* twice, *filename* must be a real file, not a stream.

--maxuniquesize positive integer

discard sequences with an abundance value greater than integer.

--minuniquesize positive integer

discard sequences with an abundance value smaller than integer.

--output filename

write the dereplicated sequences to *filename*, in fasta format and sorted by decreasing abundance. Identical sequences receive the header of the first sequence of their group. If --sizeout is used, the number of occurrences (i.e. abundance) of each sequence is indicated at the end of their fasta header using the pattern ";size=*integer*".

--sizein take into account the abundance annotations present in the input fasta file (search for the pattern "[>;]size=*integer*[;]" in sequence headers).

--sizeout add abundance annotations to the output fasta file (add the pattern ";size=*integer*" to sequence headers).

--strand plus/both

when searching for strictly identical sequences, check the *plus* strand only (default) or check *both* strands.

--topn positive integer

output only the top *integer* sequences (i.e. the most abundant).

--uc filename

output dereplication results in *filename* using a uclust-like format. See http://www.drive5.com/usearch/manual/ucout.html for a description of the format. In the context of dereplication, the option --uc_allhits has no effect.

Masking options:

An input sequence can be composed of lower- or uppercase nucleotides. Lowercase nucleotides are silently converted to uppercase before masking, unless the --qmask soft option is used. Here are the results of combined masking options --qmask (or --dbmask for database sequences) and --hardmask, assuming each input sequences contains both lower and uppercase nucleotides:

qmask	hardmask	action
none	off	no masking, lowercase converted to uppercase
none	on	idem
dust	off	masked symbols converted to lowercase, the rest converted to uppercase
dust	on	masked symbols replaced by Ns, the rest converted to upper case
soft	off	lowercase symbols considered masked, no case changes
soft	on	lowercase symbols considered masked and converted to Ns

--hardmask

mask low-complexity regions by replacing them with Ns instead of setting them to lower case.

--maskfasta filename

mask simple repeats and low-complexity regions in sequences contained in *filename*. The default is to mask using *dust* (use --qmask to modify that behavior).

--qmask none/dust/soft

mask simple repeats and low-complexity regions in sequences using the *dust* or the *soft* algorithms, or do not mask (*none*). The default is to mask using *dust*.

--output filename

write the masked sequences to filename, in fasta format.

--threads positive integer

number of computation threads to use (1 to 256). The number of threads should be lesser or equal to the number of available CPU cores. The default is to launch one thread per available logical core.

Shuffling options:

--output filename

write the shuffled sequences to filename, in fasta format.

--seed positive integer

when shuffling sequence order, use *integer* as seed. A given seed will always produce the same output order (useful for replicability). Set to 0 to use a pseudo-random seed (default behavior).

--shuffle filename

pseudo-randomly shuffle the order of sequences contained in *filename*.

--topn positive integer

output only the top integer sequences.

Sorting options:

--maxsize positive integer

when using --sortbysize, discard sequences with an abundance value greater than *integer*.

--minsize positive integer

when using --sortbysize, discard sequences with an abundance value smaller than *integer*.

--output filename

write the sorted sequences to *filename*, in fasta format.

--relabel string

relabel sequence using the prefix *string* and a ticker (1, 2, 3, etc.) to construct the new headers. Use --sizeout to conserve the abundance annotations.

--sizeout when using --relabel, report abundance annotations to the output fasta file (using the pattern ";size=*integer*").

--sortbylength filename

sort by decreasing length the sequences contained in *filename*. See the general options --minseqlength and --maxseqlength to eliminate short and long sequences.

--sortbysize filename

sort by decreasing abundance the sequences contained in *filename* (the pattern "[>;]size=*integer*[;]" has to be present). See the options --minsize and --maxsize to eliminate rare and dominant sequences.

--topn positive integer

output only the top *integer* sequences (i.e. the longest or the most abundant).

Searching options:

--alnout filename

write pairwise global alignments to *filename* using a human-readable format. Use --rowlen to modify alignment length. Output order may vary when using multiple threads.

--blast6out filename

write search results to *filename* using a blast-like tab-separated format of twelve fields (listed below), with one line per query-target matching (or lack of matching if --out-put_no_hits is used). Output order may vary when using multiple threads. A similar output can be obtain with --userout *filename* and --userfields query+target+id+alnlen+mism+opens+qlo+qhi+tlo+thi+evalue+bits. A complete list and description is available in the section "Fields" of this manual.

- 1. query: query label.
- 2. *target*: target (database sequence) label. The field is set to "*" if there is no alignment.
- 3. *id*: percentage of identity (real value ranging from 0.0 to 100.0). The percentage identity is defined as 100 * (matching columns) / (alignment length terminal gaps). See fields id0 to id4 for other definitions.
- 4. *alnlen*: length of the query-target alignment (number of columns). The field is set to 0 if there is no alignment.
- 5. *mism*: number of mismatches in the alignment (zero or positive integer value).
- 6. *opens*: number of columns containing a gap opening (zero or positive integer value).
- 7. *qlo*: first nucleotide of the query aligned with the target. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.

- 8. *qhi*: last nucleotide of the query aligned with the target. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.
- 9. *tlo*: first nucleotide of the target aligned with the query. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.
- 10. *thi*: last nucleotide of the target aligned with the query. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.
- 11. *evalue*: expectancy-value (not computed for nucleotidic alignments). Always set to -1.
- 12. bits: bit score (not computed for nucleotidic alignments). Always set to 0.

--db filename

compare query sequences (--vsearch_global) to the fasta-formatted target sequences contained in *filename*, using global pairwise alignment.

--dbmask none/dust/soft

mask simple repeats and low-complexity regions in target database sequences using the *dust* or the *soft* algorithms, or do not mask (*none*). Warning, when using *soft* masking search commands become case sensitive. The default is to mask using *dust*.

--dbmatched filename

write database target sequences matching at least one query sequence to *filename*, in fasta format. If the option --sizeout is used, the number of queries that matched each target sequence is indicated using the pattern ";size=*integer*".

--dbnotmatched filename

write database target sequences not matching query sequences to *filename*, in fasta format.

-- fastapairs filename

write pairwise alignments of query and target sequences to filename, in fasta format.

--fulldp dummy option. To maximize search sensitivity, **vsearch** uses a 8-way 16-bit SIMD vectorized full dynamic programming algorithm (Needleman-Wunsch), whether or not --fulldp is specified.

--gapext string

set penalties for a gap extension. See --gapopen for a complete description of the penalty declaration system. The default is to initialize the six gap extending penalties using a penalty of 2 for extending internal gaps and a penalty of 1 for extending terminal gaps, in both query and target sequences (i.e. 2I/1E).

--gapopen string

set penalties for a gap opening. A gap opening can occur in six different contexts: in the query (Q) or in the target (T) sequence, at the left (L) or right (R) extremity of the sequence, or inside the sequence (I). Sequence symbols (Q and T) can be combined with location symbols (L, I, and R), and numerical values to declare penalties for all possible contexts: aQL/bQI/cQR/dTL/eTI/fTR, where abcdef are null or positive integers, and "/" is use as separator.

To simplify declarations, the location symbols (L, I, and R) can be combined, the symbol (E) can be used to treat both extremities (L and R) equally, and the symbols Q and T can be ommited to treat both sequences equally. For instance, the default is to declare a penalty of 20 for opening internal gaps and a penalty of 2 for opening terminal gaps (left or right), in both query and target sequences (i.e. 20I/2E). If only a numerical value is given, without any sequence or location symbol, then the penalty applies to all gap openings. To declare an infinite penalty value, the symbol "*" can be used to indicate that gap openings are forbidden in that context.

vsearch always initializes the six gap opening penalties using the default parameters (20I/2E). The user is then free to declare only the values he wants to modify. The *string*

is scanned from left to right, accepted symbols are (0123456789/LIREQT*), and later values override previous values.

--hardmask

mask low-complexity regions by replacing them with Ns instead of setting them to lower case. For more information, please see the Masking section.

--id real reject the sequence match if the pairwise identity is lower than real (value ranging from 0.0 to 1.0 included). The search process sorts target sequences by decreasing number of k-mers they have in common with the query sequence, using that information as a proxy for sequence similarity. That efficient pre-filtering will also prevent pairwise alignments with weakly matching targets, as there needs to be at least 6 shared k-mers to start the pairwise alignment, and at least one out of every 16 k-mers from the query needs to match the target. Consequently, using values lower than --id 0.5 is not likely to capture more weakly matching targets. The pairwise identity is defined as the number of (matching columns) / (alignment length - terminal gaps). That definition can be modified by --iddef.

--iddef 0/1/2/3/4

change the pairwise identity definition used in --id. Values accepted are:

- 0. CD-HIT definition using shortest sequence as numerator.
- 1. edit distance.
- 2. edit distance excluding terminal gaps (default value of --id).
- 3. Marine Biological Lab definition counting each extended gap as a single difference.
- 4. BLAST definition, equivalent to --iddef 2 in a context of global pairwise alignment.

The option --userfields accepts the fields id0 to id4, in addition to the field id, to report the pairwise identity values corresponding to the different definitions.

--idprefix positive integer

reject the target sequence if the first *integer* nucleotides do not match the query sequence.

--idsuffix positive integer

reject the target sequence if the last *integer* nucleotides do not match the query sequence.

--leftjust reject the target sequence if the alignment begins with gaps.

--match integer

score assigned to a match (i.e. identical nucleotides) in the pairwise alignment. The default value is 2.

--matched filename

write query sequences matching database target sequences to filename, in fasta format.

--maxaccepts positive integer

maximum number of hits to accept before stopping the search. The default value is 1. That option works in pair with maxrejects. The search process sorts target sequences by decreasing number of k-mers they have in common with the query sequence, using that information as a proxy for sequence similarity. If the first target sequence passes the acceptation criteria, it is accepted as best hit and the search process stops for that query. If maxaccepts is set to a higher value, more hits are accepted. If maxaccepts and maxrejects are both set to 0, the complete database is searched.

--maxdiffs positive integer

reject the target sequence if the alignment contains at least *integer* substitutions, insertions or deletions.

--maxgaps positive integer

reject the target sequence if the alignment contains at least *integer* insertions or deletions

--maxhits positive integer

maximum number of hits to show once the search is terminated (hits are sorted by decreasing identity). Unlimited by default value. **It applies to almout, blast6out, uc, userout, fastapairs**.

--maxid real

reject the target sequence if its percentage of identity with the query is equal to or greater than *real*.

--maxqsize positive integer

reject query sequences with an abundance equal to or greater than integer.

--maxqt real

reject if the query/target sequence length ratio is equal to or greater than *real*.

-- maxrejects positive integer

maximum number of non-matching target sequences to consider before stopping the search. The default value is 32. That option works in pair with maxaccepts. The search process sorts target sequences by decreasing number of k-mers they have in common with the query sequence, using that information as a proxy for sequence similarity. If none of the first 32 target sequences pass the acceptation criteria, the search process stops for that query (no hit). If maxrejects is set to a higher value, more target sequences are considered. If maxaccepts and maxrejects are both set to 0, the complete database is searched.

--maxsizeratio real

reject if the query/target abundance ratio is equal to or greater than real.

--maxsl real

reject if the shorter/longer sequence length ratio is equal to or greater than real.

--maxsubs positive integer

reject the target sequence if the alignment contains at least *integer* substitutions.

--mid real

reject the alignment if the percentage of identity is lower than *real* (ignoring all gaps, internal and terminal).

--mincols positive integer

reject the target sequence if the alignment length is shorter than integer.

--minqt real

reject if the query/target sequence length ratio is lower than real.

--minsizeratio real

reject if the query/target abundance ratio is lower than real.

--minsl real

reject if the shorter/longer sequence length ratio is lower than real.

--mintsize positive integer

reject target sequences with an abundance lower than integer.

--mismatch integer

score assigned to a mismatch (i.e. different nucleotides) in the pairwise alignment. The default value is -4.

--notmatched filename

write query sequences not matching database target sequences to filename, in fasta format

--output_no_hits

write both matching and non-matching queries to --alnout, --blast6out, and --userout output files (--uc and --uc_allhits output files always feature non-matching queries). Non-matching queries are labelled "No hits" in --alnout files.

--qmask none/dust/soft

mask simple repeats and low-complexity regions in query sequences using the *dust* or the *soft* algorithms, or do not mask (*none*). Warning, when using *soft* masking search commands become case sensitive. The default is to mask using *dust*.

--query_cov real

reject if the fraction of the query aligned to the target sequence is lower than real. The query coverage is computed as such: 100.0 * (matches + mismatches) / query sequence length. Internal or terminal gaps are not taken into account.

-- rightjust

reject the target sequence if the alignment ends with gaps.

--rowlen positive integer

width of alignment lines in --alnout output. The default value is 64. Set to 0 to eliminate the wrapping.

- **--self** reject the alignment if the query and target labels are identical.
- **--selfid** reject the alignment if the query and target sequences are strictly identical.
- **--sizeout** add abundance annotations to the output of the option --dbmatched (using the pattern ";size=*integer*").

--strand plus/both

when searching for similar sequences, check the *plus* strand only (default) or check *both* strands.

--target_cov real

reject if the fraction of the target sequence aligned to the query sequence is lower than *real*. The target coverage is computed as such: 100.0 * (matches + mismatches) / target sequence length. Internal or terminal gaps are not taken into account.

--threads positive integer

number of computation threads to use (1 to 256). The number of threads should be lesser or equal to the number of available CPU cores. The default is to launch one thread per available logical core.

--top_hits_only

output only the hits with the highest percentage of identity with the query.

--uc filename

output searching results in *filename* using a uclust-like format. See http://www.drive5.com/usearch/manual/ucout.html for a description of the format. Output order may vary when using multiple threads.

--uc allhits

when using the --uc option, show all hits, not just the top hit for each query. **TO BE TESTED**.

--userfields string

when using --userout, select and order the fields written to the output file. Fields are separated by "+" (e.g. query+target+id). See the next section for a complete list of fields.

--userout filename

write user-defined tab-separated output to *filename*. Select the fields with the option --userfields. Output order may vary when using multiple threads. If --userfields is empty or not present, *filename* is empty.

--vsearch_global filename

compare target sequences (--db) to the fasta-formatted query sequences contained in *filename*, using global pairwise alignment.

--weak id real

show hits with percentage of identity of at least *real*, without terminating the search. A normal search stops as soon as enough hits are found (as defined by --maxaccepts, --maxrejects, and --id). As --weak_id reports weak hits that are not deduced from --maxaccepts, high --id values can be used, hence preserving both speed and sensitivity. Logically, *real* must be smaller than the value indicated by --id.

--wordlength positive integer

length of words (i.e. *k*-mers) for database indexing. The range of possible values goes from 3 to 15, but values near 8 are generally recommended. Longer words may reduce the sensitivity for weak similarities, but can increase accuracy. On the other hand, shorter words may increase sensitivity, but can reduce accuracy. Computation time will generally increase with shorter words and decrease with longer words. Memory requirements for a part of the index increase with a factor of 4 each time word length increases by one nucleotide, and this generally becomes significant for long words (12 or more). The default value is 8.

Fields accepted by the --userfields option:

aln Print a string of M (match), D (delete, i.e. a gap in the query) and I (insert, i.e. a gap in the target) representing the pairwise alignment. Empty field if there is no alignment.

alnlen Print the length of the query-target alignment (number of columns). The field is set to 0 if there is no alignment.

bits Bit score (not computed for nucleotidic alignments). Always set to 0.

caln Compact representation of the pairwise alignment using the CIGAR format (Compact Idiosyncratic Gapped Alignment Report): M (match), D (deletion) and I (insertion). Empty field if there is no alignment.

exts Number of columns containing a gap extension (zero or positive integer value).

gaps Number of columns containing a gap (zero or positive integer value).

id Percentage of identity (real value ranging from 0.0 to 100.0). The percentage identity is defined as 100 * (matching columns) / (alignment length - terminal gaps).

id0 CD-HIT definition of the percentage of identity, using the shortest sequence in the pairwise alignment as numerator (real value ranging from 0.0 to 100.0).

id1 The percentage of identity (real value ranging from 0.0 to 100.0) is defined as the edit distance: 100 * (matching columns) / (alignment length).

id2 The percentage of identity (real value ranging from 0.0 to 100.0) is defined as the edit distance, excluding terminal gaps. The field id2 is an alias for the field id.

id3 Marine Biological Lab definition of the percentage of identity (real value ranging from 0.0 to 100.0), counting each extended gap as a single difference.

id4 BLAST definition of the percentage of identity (real value ranging from 0.0 to 100.0), equivalent to --iddef 2 in a context of global pairwise alignment.

ids Number of matches in the alignment (zero or positive integer value).

mism Number of mismatches in the alignment (zero or positive integer value).

opens Number of columns containing a gap opening (zero or positive integer value).

pairs Number of columns containing only nucleotides. That value corresponds to the length of the alignment minus the gap-containing columns (zero or positive integer value).

pctgaps Number of columns containing gaps expressed as a percentage of the alignment length (real value ranging from 0.0 to 100.0).

pctpv Percentage of positive columns. When working with nucleotidic sequences, this is equivalent to the percentage of matches (real value ranging from 0.0 to 100.0).

pv Number of positive columns. When working with nucleotidic sequences, this is equivalent to the number of matches (zero or positive integer value).

qcov Fraction of the query sequence that is aligned with the target sequence (real value ranging from 0.0 to 100.0). The query coverage is computed as such: 100.0 * (matches + mismatches) / query sequence length. Internal or terminal gaps are not taken into account. The field is set to 0.0 if there is no alignment.

qframe Query frame (-3 to +3). That field only concerns coding sequences and is not computed by **vsearch**. Always set to +0.

qhi Last nucleotide of the query aligned with the target. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.

ql Query sequence length (positive integer value). The field is set to 0 if there is no alignment.

qlo First nucleotide of the query aligned with the target. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.

qrow Print the sequence of the query segment as seen in the pairwise alignment (i.e. with gap insertions if need be). Empty field if there is no alignment.

qs Query segment length. Always equal to query sequence length.

qstrand Query strand orientation (+ or - for nucleotidic sequences). Empty field if there is no alignment.

query Query label.

raw Raw alignment score (negative, null or positive integer value). The score is the sum of match rewards minus mismatch penalties, gap openings and gap extensions. The field is set to 0 if there is no alignment.

target Target label. The field is set to "*" if there is no alignment.

fraction of the target sequence that is aligned with the query sequence (real value ranging from 0.0 to 100.0). The target coverage is computed as such: 100.0 * (matches + mismatches) / target sequence length. Internal or terminal gaps are not taken into account. The field is set to <math>0.0 if there is no alignment.

tframe Target frame (-3 to +3). That field only concerns coding sequences and is not computed by **vsearch**. Always set to +0.

thi Last nucleotide of the target aligned with the query. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.

tl Target sequence length (positive integer value). The field is set to 0 if there is no alignment.

tlo First nucleotide of the target aligned with the query. Nucleotide numbering starts from 1. The field is set to 0 if there is no alignment.

trow Print the sequence of the target segment as seen in the pairwise alignment (i.e. with gap insertions if need be). Empty field if there is no alignment.

ts Target segment length. Always equal to target sequence length. The field is set to 0 if there is no alignment.

tstrand Target strand orientation (+ or - for nucleotidic sequences). Always set to "+", so reverse strand matches have tstrand "+" and qstrand "-". Empty field if there is no alignment.

DELIBERATE CHANGES

If you are a usearch user, our objective is to make you feel at home. That's why **vsearch** was designed to behave like usearch, to some extend. Like any complex software, usearch is not free from quirks and inconsistencies. We decided not to reproduce some of them, and for complete transparency, to document here the deliberate changes we made.

During a search with usearch, when using the options --blast6out and --output_no_hits, for queries with no match the number of fields reported is 13, where it should be 12. This is corrected in **vsearch**.

The fields qlo, qhi, tlo, thi and raw of the --userfields option are not informative in usearch. This is corrected in **vsearch**.

In usearch, when using the option --output_no_hits, queries that receive no match are reported in blast6out file, but not in the alignment output file. This is corrected in **vsearch**.

vsearch reintroduces with --iddef alternative pairwise identity definitions that were removed from usearch.

vsearch extends the --topn option to sorting commands.

vsearch extends the --rowlen option to the chimera command (--uchimealns option).

NOVELTIES

vsearch introduces new options not present in usearch. They are described in the "Options" section of this manual. Here is a short list:

- · shuffle
- · fasta width
- iddef
- maxuniquesize

EXAMPLES

Clusterize with a 97% similarity threshold, collect cluster centroids, and write cluster descriptions using a uclust-like format:

vsearch --cluster_fast queries.fas --id 0.97 --centroids centroids.fas --uc clusters.uc

Dereplicate the sequences contained in queries.fas, take into account the abundance information already present, write unwrapped sequences to output with the new abundance information, discard all sequences with an abundance of 1:

vsearch --derep_fulllength *queries.fas* --output *queries_masked.fas* --sizein --sizeout --fasta_width 0 --minuniquesize 2

Mask simple repeats and low complexity regions in the input fasta file (masked regions are lowercased), and write the results to the output file:

vsearch --maskfasta queries.fas --output queries_masked.fas --qmask soft

Sort by decreasing abundance the sequences contained in queries.fas (using the "size=*integer*" information), relabel the sequences while preserving the abundance information (with --sizeout), keep only sequences with an abundance equal to or greater than 2:

vsearch --sortbysize *queries.fas* --output *queries_sorted.fas* --relabel sampleA_ --sizeout --min-size 2

Search queries in a reference database, with a 80%-similarity threshold, take terminal gaps into account

when calculating pairwise similarities:

vsearch --vsearch_global queries.fas --db references.fas --alnout results.aln --id 0.8 --iddef 1

Search a sequence dataset against itself (ignore self hits), get all matches with at least 60% identity, and collect results in a blast-like tab-separated format:

vsearch --vsearch_global *queries.fas* --db *queries.fas* --id 0.6 --self --blast6out *results.blast6* --maxaccepts 0 --maxrejects 0

Shuffle the input fasta file (change the order of sequences) in a repeatable fashion (fixed seed), and write unwrapped fasta sequences to the output file:

vsearch --shuffle queries.fas --output queries_shuffled.fas --seed 13 --fasta_width 0

LIMITATIONS

vsearch does not yet perform chimera detection.

AUTHORS

Implementation by Torbjørn Rognes and Tomas Flouri, documentation by Frédéric Mahé.

REPORTING BUGS

Submit suggestions and bug-reports at https://github.com/torognes/vsearch/issues, send a pull request on https://github.com/torognes/vsearch, or compose a friendly or curmudgeont e-mail to Torbjørn Rognes torognes@ifi.uio.no.
